

- paper-level variables: metadata to get from initial screening
 - Survey experiment - most of the time if its a survey experiment, they say "experiment"
 - For experiment type, look at research, methodology, design, research design, etc
 - Keep in mind number number of surveys, sometimes stated in abstract/beginning
 - First author's discipline often requires outside web search
 - Prolific is an online survey website - other common survey websites?
 - Qualtrics, yougov, m-turk, CloudSearch, Cint
 - Also consider asking model to look for words corresponding with "common survey platforms" (depends what model we use and if it has that specialized knowledge)
 - Factual info provided as stimulus vs none
 - manipulation / attention checks - used to verify paying attention in surveys
 - Search for "attention check, manipulation check, comprehension check, focus" in paper and look at survey questions themselves - also often mentioned in methods, also search for "weights"
 - Survey questions provided? + In paper vs hyperlink
 - Response measurement - look for Likert scale/measurement
 - Recording options and don't knows / not sures - how to avoid hallucination?
-
- If words like experiments, controls, treatments, conditions are not included in paper, its likely to be a regular survey and not an experiment
 - Methodology - tends to give the most info
 - Use key locations to infer country (e.g. Uni of Waterloo)
 - Probability samples
 - How to get the right dates - make sure AI doesnt mistake survey dates for acceptance date (when paper was accepted for publishing) and publication dates
 - Ignore demographic questions in survey if present - only code questions after those
 - the presence of a statement saying that multiple surveys were conducted leads to experiment vs a single survey
 - Question interpretation may be order dependent
 - Composite index - summary score of a certain measurement: average, cronbach's alpha, factor analysis, principal component analysis, reliability 0-1
-
- Have AI create spreadsheet with all questions
 - Two aspects - population and interpretation (of information)
 - Prioritize easiest variables + highest returns
 - Evidence of where it extracted the variables
 - Flag for human-coded vs AI coded for validation
